You may be able to find more information about this and similar content in piano.io A healthy body like a well-maintained car: It operates at peak performance during fuel. The body is diabetic, on the other hand, like a car with a faulty fuel injector: Gas may be in the tank, but it does not reach the engine. When you eat, the food is broken down into simple sugars called glucose, which quickly enter your bloodstream. Then insulin, a hormone produced by the pancreas, delivers blood glucose to individual cells, where it is used to move the entire body. The amount of insulin produced is directly proportional to the amount of glucose in the blood. This allows the body to utilize most of the energy supplied by food. But blood glucose can't move the body unless insulin sends it to cells. Because diabetics either do not produce insulin (called Type 1 diabetes) or have cells that develop resistance to hormones (known as Type 2), the fuel that goes into the body is not used. Instead the cells are left hungry, causing fatigue, dizziness, confusion, or fainting spells. Sugar builds up in the bloodstream and becomes toxic over time, eventually damaging the eyes, kidneys, nervous system, immune system, blood vessels, and heart. The disease shaves 8 years off the lives of the average man. This content is created and managed by third parties, and is imported into this page to help users provide their email addresses.
